

**Lecture Note of Bus 41202, Spring 2006:
GARCH Models. Mr. Ruey Tsay**

Conditional Heteroscedastic Models

What is stock volatility?

Answer: conditional standard deviation of stock returns

Why is volatility important?

Has many important applications

- Option (derivative) pricing
- Risk management, e.g. value at risk (VaR)
- Asset allocation
- Interval forecasts

Black-Scholes European call option:

$$c_t = P_t \Phi(x) - Kr^{-\ell} \Phi(x - \sigma_t \sqrt{\ell})$$

$$x = \frac{\ln(P_t / Kr^{-\ell})}{\sigma_t \sqrt{\ell}} + \frac{1}{2} \sigma_t \sqrt{\ell}$$

- P_t : current price of the stock,
- r : risk-free interest rate,
- K : strike price

- ℓ : time to expiration
- σ_t : conditional standard deviation of the log return of the specified stock,
- $\Phi(x)$: normal CDF

A key characteristic: Not directly observable!!

How to calculate volatility?

1. Use high-frequency data: French, Schwert & Stambaugh (1987); see Section 3.15.
 - Realized volatility in recent literature.
 - Use daily high, low, and closing prices.
2. Implied volatility of options data, e.g, VIX of CBOE. See Figure 1.
3. Econometric modeling

We focus on the econometric modeling first. Use of high frequency data will be discussed later.

Basic idea of econometric modeling

Shocks of asset returns are NOT serially correlated, but dependent. See ACF of squared and absolute returns of some stocks

Basic structure

$$r_t = \mu_t + a_t, \quad \mu_t = \phi_0 + \sum_{i=1}^p \phi_i r_{t-i} - \sum_{i=1}^q \theta_i a_{t-i},$$

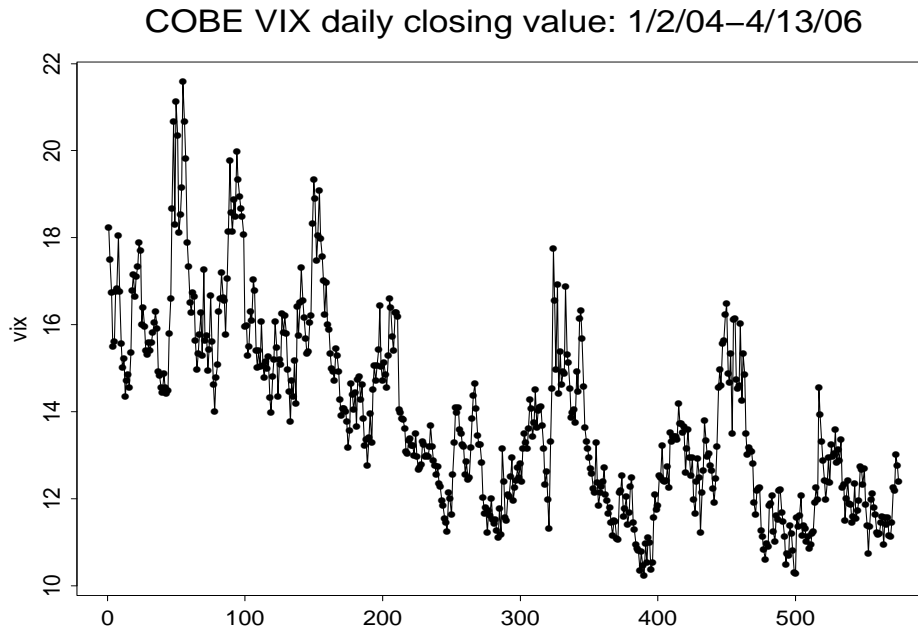

Figure 1: Time plot of the daily closing value of VIX of the COBE: January 2, 2004 to April 13, 2006.

Volatility models are concerned with time-evolution of

$$\sigma_t^2 = \text{Var}(r_t|F_{t-1}) = \text{Var}(a_t|F_{t-1}).$$

the conditional variance of a return.

Two general categories

- “Fixed function” and
- Stochastic function

of the available information.

Univariate volatility models

1. Autoregressive conditional heteroscedastic (ARCH) model of Engle (1982),

2. Generalized ARCH (GARCH) model of Bollerslev (1986),
3. GARCH-M models
4. IGARCH models
5. Exponential GARCH (EGARCH) model of Nelson (1991),
6. Threshold GARCH model of Zakoian (1994) or GJR model of Glosten, Jagannathan, and Runkle (1993).
7. Conditional heteroscedastic ARMA (CHARMA) model of Tsay (1987),
8. Random coefficient autoregressive (RCA) model of Nicholls and Quinn (1982)
9. Stochastic volatility (SV) models of Melino and Turnbull (1990), Harvey, Ruiz and Shephard (1994), and Jacquier, Polson and Rossi (1994).

ARCH model

$$a_t = \sigma_t \epsilon_t, \quad \sigma_t^2 = \alpha_0 + \alpha_1 a_{t-1}^2 + \cdots + \alpha_m a_{t-m}^2,$$

where $\{\epsilon_t\}$ is a sequence of iid r.v. with mean 0 and variance 1, $\alpha_0 > 0$ and $\alpha_i \geq 0$ for $i > 0$.

Distribution of ϵ_t : Standard normal, standardized Student-t, generalized error dist (GED), or skewed Student-t.

Properties of ARCH models

Consider an ARCH(1) model

$$a_t = \sigma_t \epsilon_t, \quad \sigma_t^2 = \alpha_0 + \alpha_1 a_{t-1}^2,$$

where $\alpha_0 > 0$ and $\alpha_1 \geq 0$.

1. $E(a_t) = 0$
2. $\text{Var}(a_t) = \alpha_0 / (1 - \alpha_1)$ if $0 < \alpha_1 < 1$
3. Under normality,

$$m_4 = \frac{3\alpha_0^2(1 + \alpha_1)}{(1 - \alpha_1)(1 - 3\alpha_1^2)},$$

provided $0 < \alpha_1^2 < 1/3$.

The 3rd property implies heavy tails.

Advantages

- Simplicity
- Generates volatility clustering
- Heavy tails (high kurtosis)

Weaknesses

- Symmetric btw positive & negative prior returns
- Restrictive
- Provides no explanation
- Not sufficiently adaptive in prediction

Building an ARCH Model

1. Modeling the mean effect and testing

Use Q-statistics of squared residuals; McLeod and Li (1983) & Engle (1982)

2. Order determination

Use PACF of the squared residuals

3. Estimation: Conditional MLE

4. Model checking: Q-stat of standardized residuals and squared standardized residuals. Skewness & Kurtosis of standardized residuals.

5. Software: Many available. We use R and S-Plus in class.

Estimation: (Understand the concept!)

Under normality, the likelihood function of an ARCH(m) model is $f(a_1, \dots, a_T | \boldsymbol{\alpha})$

$$\begin{aligned} &= f(a_T | F_{T-1}) f(a_{T-1} | F_{T-2}) \cdots f(a_{m+1} | F_m) f(a_1, \dots, a_m | \boldsymbol{\alpha}) \\ &= \prod_{t=m+1}^T \frac{1}{\sqrt{2\pi\sigma_t^2}} \exp\left[-\frac{a_t^2}{2\sigma_t^2}\right] \times f(a_1, \dots, a_m | \boldsymbol{\alpha}), \end{aligned}$$

where $\boldsymbol{\alpha} = (\alpha_0, \alpha_1, \dots, \alpha_m)'$ and $f(a_1, \dots, a_m | \boldsymbol{\alpha})$ is the joint pdf of a_1, \dots, a_m .

A conditional log likelihood function is

$$\ell(a_{m+1}, \dots, a_T | \boldsymbol{\alpha}, a_1, \dots, a_m)$$

$$- \sum_{t=m+1}^T \left[\frac{1}{2} \ln(\sigma_t^2) + \frac{1}{2} \frac{a_t^2}{\sigma_t^2} \right],$$

where $\sigma_t^2 = \alpha_0 + \alpha_1 a_{t-1}^2 + \dots + \alpha_m a_{t-m}^2$ can be evaluated recursively.

Under t -dist, the cond. log likelihood fun. is

$$\begin{aligned} & \ell(a_{m+1}, \dots, a_T | \boldsymbol{\alpha}, A_m) \\ &= - \sum_{t=m+1}^T \left[\frac{v+1}{2} \ln \left(1 + \frac{a_t^2}{(v-2)\sigma_t^2} \right) + \frac{1}{2} \ln(\sigma_t^2) \right], \end{aligned}$$

if v is given.

Otherwise, it becomes $\ell(a_{m+1}, \dots, a_T | \boldsymbol{\alpha}, v, A_m)$

$$\begin{aligned} &= (T - m) [\ln(\Gamma((v+1)/2)) - \ln(\Gamma(v/2)) - 0.5 \ln((v-2)\pi)] \\ & \quad + \ell(a_{m+1}, \dots, a_T | \boldsymbol{\alpha}, A_m). \end{aligned}$$

Example: Monthly log returns of Intel stock

R demonstration:

Special Note: R uses “OX” package with “garchOxFit” command to estimate GARCH models. The GARCH order in OX is different from that of the textbook and S-Plus. A GARCH(r, m) model in the textbook and S-Plus is called a GARCH(m, r) model in R. In other words, ARCH order is the 2nd argument in R.

```
> library(fSeries)
> source("garchoxfit.R") % Modification needed to make the program working.
> da=read.table("m-intc7303.txt")
> intc=ts(log(da[,2]+1),frequency=12,start=c(1973,1)) % log returns
> acf(intc)
> acf(intc^2)
> pacf(intc)
> pacf(intc^2)
```

```

> Box.test((intc)^2,lag=10,type='Ljung') % Test for ARCH effect.
      Box-Ljung test

[1] 0.1393796

> qqnorm(sresi) % Normal probability plot to check normal assumption
> qqline(sresi) % add line to help read the plot.

```

From the R output, we obtain that, under normality,

$$r_t = 0.0165 + a_t, \quad \sigma_t^2 = 0.012 + 0.374a_{t-1}^2.$$

Model checking:

Standardized shocks $\{\tilde{a}_t\}$

$$Q(10) = 13.67(0.19)$$

For $\{\tilde{a}_t^2\}$

$$Q(10) = 12.26(0.20), \text{ but } Q(15) = 29.70(.01)$$

Implications

- Expected monthly log return is about 1.7%.
- $\hat{\alpha}_1^2 = 0.374^2 < 1/3$ so that 4th moment exists.

From the S-Plus output, we obtain that, under normality,

$$r_t = 0.0174 + a_t, \quad \sigma_t^2 = 0.013 + 0.353a_{t-1}^2.$$

Model checking:

Standardized shocks $\{\tilde{a}_t\}$

$$Q(12) = 15.37(0.22)$$

For $\{\tilde{a}_t^2\}$

$$Q(12) = 21.28(.01).$$

The two programs give similar, but not identical, results.

Next, consider Student-t innovations.

Question: What is the fitted ARCH(1) model in R?

$$r_t = 0.022 + a_t, \quad \sigma_t^2 = 0.013 + 0.268a_{t-1}^2,$$

and the t-distribution has 6.00 d.f.

Question: What is the fitted ARCH(1) model in S-Plus?

$$r_t = 0.022 + a_t, \quad \sigma_t^2 = 0.013 + 0.249a_{t-1}^2,$$

and the t-distribution has 6.16 d.f.

Comparison with normal models:

- Using a heavy-tailed dist for ϵ_t reduces the ARCH effect
- The difference between the models is small for this particular instance.

You may try the generalized error distribution.

GARCH Model

$$a_t = \sigma_t \epsilon_t,$$
$$\sigma_t^2 = \alpha_0 + \sum_{i=1}^m \alpha_i a_{t-i}^2 + \sum_{j=1}^s \beta_j \sigma_{t-j}^2$$

where $\{\epsilon_t\}$ is defined as before, $\alpha_0 > 0$, $\alpha_i \geq 0$, $\beta_j \geq 0$, and $\sum_{i=1}^{\max(m,s)} (\alpha_i + \beta_i) < 1$.

Re-parameterization:

Let $\eta_t = a_t^2 - \sigma_t^2$. $\{\eta_t\}$ un-correlated series.

The GARCH model becomes

$$a_t^2 = \alpha_0 + \sum_{i=1}^{\max(m,s)} (\alpha_i + \beta_i) a_{t-i}^2 + \eta_t - \sum_{j=1}^s \beta_j \eta_{t-j}.$$

This is an ARMA form for the squared series a_t^2 .

Use it to understand properties of GARCH models, e.g. moment equations, forecasting, etc.

Focus on a GARCH(1,1) model

$$\sigma_t^2 = \alpha_0 + \alpha_1 a_{t-1}^2 + \beta_1 \sigma_{t-1}^2,$$

- Weak stationarity: $0 \leq \alpha_1, \beta_1 \leq 1, (\alpha_1 + \beta_1) < 1$.

- Volatility clusters
- Heavy tails: if $1 - 2\alpha_1^2 - (\alpha_1 + \beta_1)^2 > 0$, then

$$\frac{E(a_t^4)}{[E(a_t^2)]^2} = \frac{3[1 - (\alpha_1 + \beta_1)^2]}{1 - (\alpha_1 + \beta_1)^2 - 2\alpha_1^2} > 3.$$

- For 1-step ahead forecast,

$$\sigma_h^2(1) = \alpha_0 + \alpha_1 a_h^2 + \beta_1 \sigma_h^2.$$

For multi-step ahead forecasts, use $a_t^2 = \sigma_t^2 \epsilon_t^2$ and rewrite the model as

$$\sigma_{t+1}^2 = \alpha_0 + (\alpha_1 + \beta_1) \sigma_t^2 + \alpha_1 \sigma_t^2 (\epsilon_t^2 - 1).$$

2-step ahead volatility forecast

$$\sigma_h^2(2) = \alpha_0 + (\alpha_1 + \beta_1) \sigma_h^2(1).$$

In general, we have

$$\sigma_h^2(\ell) = \alpha_0 + (\alpha_1 + \beta_1) \sigma_h^2(\ell - 1), \quad \ell > 1.$$

This result is exactly the same as that of an ARMA(1,1) model with AR polynomial $1 - (\alpha_1 + \beta_1)B$.

Example: Monthly excess returns of S&P 500 index starting from 1926 for 792 observations.

The fitted of a Gaussian AR(3) model

$$r_t = .088r_{t-1} - .023r_{t-2} - .123r_{t-3} + .007 + a_t,$$

$$\hat{\sigma}_a^2 = 0.00333.$$

For the GARCH effects, use a GARCH(1,1) model (R output).

A joint estimation:

$$\begin{aligned} r_t &= 0.032r_{t-1} - 0.030r_{t-2} - 0.010r_{t-3} + 0.0076 + a_t \\ \sigma_t^2 &= .00008 + .853\sigma_{t-1}^2 + 0.125a_{t-1}^2. \end{aligned}$$

Implied unconditional variance of a_t is

$$\frac{0.0000794}{1 - 0.85298 - 0.1247} = 0.00356$$

close to the expected value.

A simplified model:

$$r_t = 0.0074 + a_t, \sigma_t^2 = .00008 + .854\sigma_{t-1}^2 + .122a_{t-1}^2.$$

Model checking:

For \tilde{a}_t : $Q(10) = 11.22(0.34)$ and $Q(20) = 24.29(0.23)$.

For \tilde{a}_t^2 : $Q(10) = 9.92(0.27)$ and $Q(20) = 16.74(0.54)$.

Forecast: 1-step ahead forecast:

$$\sigma_h^2(1) = 0.00008 + 0.854\sigma_h^2 + 0.122a_h^2$$

Horizon	1	2	3	4	5	∞

```

Compare the Splus result with that of R!

Turn to Student-t innovation.

Estimation of degrees of freedom:

$$r_t = 0.0085 + a_t,$$

$$\sigma_t^2 = .00012 + .113a_{t-1}^2 + .842\sigma_{t-1}^2,$$

where the estimated degrees of freedom is 6.99.

Forecasting evaluation

Not easy to do; see Andersen and Bollerslev (1998).

IGARCH model

An IGARCH(1,1) model:

$$a_t = \sigma_t \epsilon_t, \sigma_t^2 = \alpha_0 + \beta_1 \sigma_{t-1}^2 + (1 - \beta_1) a_{t-1}^2.$$

For the monthly excess returns of the S&P 500 index, we have

$$r_t = .007 + a_t, \sigma_t^2 = .0001 + .806\sigma_{t-1}^2 + .194a_{t-1}^2$$

For an IGARCH(1,1) model,

$$\sigma_h^2(\ell) = \sigma_h^2(1) + (\ell - 1)\alpha_0, \quad \ell \geq 1,$$

where h is the forecast origin.

Effect of $\sigma_h^2(1)$ on future volatilities is persistent, and the volatility forecasts form a straight line with slope α_0 . See Nelson (1990) for more info.

Special case: $\alpha_0 = 0$.

used in RiskMetrics to VaR calculation.

Example: An IGARCH(1,1) model for the monthly excess returns of S&P500 index from 1926 to 1991 is given below via R.

$$r_t = 0.0074 + a_t, \quad a_t = \sigma_t \epsilon_t$$

$$\sigma_t^2 = .00005 + .143a_{t-1}^2 + .857\sigma_{t-1}^2.$$

Q-Statistics on Standardized Residuals

Q(10) = 10.8290 [0.3709943]
Q(15) = 17.6387 [0.2821344]
Q(20) = 23.6418 [0.2583909]

Q-Statistics on Squared Standardized Residuals

--> P-values adjusted by 2 degree(s) of freedom
 Q(10) = 10.0513 [0.2614457]
 Q(15) = 13.4740 [0.4119030]
 Q(20) = 15.9382 [0.5968584]

The GARCH-M model

$$r_t = \mu + c\sigma_t^2 + a_t, \quad a_t = \sigma_t\epsilon_t, \sigma_t^2 = \alpha_0 + \alpha_1 a_{t-1}^2 + \beta_1 \sigma_{t-1}^2$$

where c is referred to as risk premium, which is expected to be positive.

Example: A GARCH(1,1)-M model for the monthly excess returns of S&P 500 index from January 1926 to December 1991. The fitted model is

$$r_t = 0.0054 + 1.01\sigma_t^2 + a_t, \sigma_t^2 = .00008 + .123a_{t-1}^2 + .852\sigma_{t-1}^2.$$

Std err of risk premium is 0.753.
