Labor Market Fluidity and Economic Performance

Steven J. Davis
University of Chicago Booth School of Business & NBER

Based on Research with John Haltiwanger

National Association of Business Economists
Chicago IL, 28 September 2014
Main Themes and Results

1. **U.S. labor markets became much less fluid in recent decades**
   - Fluidity declines hold across states, industries, firm size and age categories, and demographic groups defined by age, gender and education.

2. **Many contributing factors, including:**
   - Shift of activity to older firms and establishments
   - Shift to larger firms and establishments in some sectors (e.g., Retail Trade)
   - An aging workforce
   - Policy developments that suppress reallocation (e.g., erosion of employment-at-will)

3. **Reasons for Concern:**
   - Worker and job reallocation contribute to productivity and real wage growth
   - Reduced fluidity negatively affects employment, especially for those with limited skills

4. **Key Implication for U.S. economic outlook:**
   - U.S. faced serious impediments to high employment before the Great Recession. A return to sustained high employment unlikely without restoring labor market fluidity

Annual Rates of Job Reallocation Across Firms and Establishments, U.S. Nonfarm Private Sector

Worker Reallocation = Job Reallocation + Churn
(Hires + Separations) (Creation + Destruction)
Annual Job Reallocation Rates in Selected U.S. Industry Sectors

Employment Share of Firms Five Years Old or Younger
Why the Decline in Labor Market Fluidity?

• A shift to older firms and establishments accounts for a quarter of the decline in job reallocation intensity since the early 1980s
• A shift to larger businesses played an important role in retail trade.
• Shifts in the industry distribution of employment go the “wrong” way.
• Taken together, shifts in the industry, age and size distribution of employment account for about 15% of the secular drop in job reallocation
• An aging workforce contributes to the decline in worker reallocation intensity – a bigger factor in the 1980s and early 1990s than 2000s
• Policy developments also suppressed labor market fluidity:
  • Occupational restrictions in the form of government-mandated licensing and certification requirements grew from 5% of jobs in 1950s to 38% by 2008
  • Erosion of employment-at-will doctrine
  • Expansion of protected classes of workers (age, race, disability, etc.)
  • “Job lock” associated with employer-provided health insurance
  • As yet, we know little about how much these policy factors suppressed fluidity
Is Reduced Fluidity Cause for Concern?

1. Beneficial and benign aspects of reduced fluidity:
   A. Less job reallocation means fewer layoffs and smaller unemployment inflows.
   B. Reduced fluidity is partly a by-product of developments that raised productivity and improved welfare: The shift away from small, independent stores to big box retailers raised productivity, lowered prices, and increased product selection. This shift to larger firms and establishments brought lower rates of reallocation.

2. Reasons for concern:
   A. Reallocation plays a key role in prominent theories of innovation and growth.
   B. Factor reallocation flows are an important source of medium-term productivity growth according to many empirical studies.
   C. Fluidity facilitates job mobility, wage growth and career advancement.
   D. Fluidity promotes high employment. (New evidence in our work.)
The Fluid Labor Markets Hypothesis

Hypothesis: Fluid labor markets promote high employment.

Mechanisms:

1. **Job creation incentives** (Rob Shimer, 2001): Young workers tend to be less well matched to suitable jobs than older workers. When the youth share of the working-age population is high, average match quality is low, and employers with open job positions are more likely to encounter poorly matched workers. Easier recruiting, in turn, leads to higher equilibrium job creation and lower unemployment rates for workers of all ages.

2. **Human Capital Accumulation:** Fluid labor markets offer abundant opportunities to find a job, prospect for the “right” job, move up a job ladder, satisfy locational constraints, re-enter the labor market, etc. The result is better opportunities and stronger incentives to accumulate market-relevant human capital, increasing earnings capacity and strengthening work attachment. (The effects on employment are especially relevant for younger and marginal workers, and those with limited skills.)

3. My paper with Haltiwanger discusses other mechanisms as well.
How We Assess the Fluid Labor Markets Hypothesis

1. Estimate effects of fluidity on state-level employment rates for groups defined by gender, education, and age.
   • Use variation over time within states and demographic groups

2. Baseline Regression Specification:
   • Three-year averages of all variables
   • Controls for state fixed effects, and for national and state-level cyclical conditions
   • Additional controls for presence of children and young children in the HH

3. Instrument fluidity variables to address measurement error, endogeneity concerns, and retain focus on longer-term effects. Instruments:
   • Share of working-age population 18-24 years old in the state and time period
   • Abundance of less educated persons 25-31 in the state and time period: relative to working-age population, and relative to population 25-31
   • Reallocation intensity measures that derive from national shifts in the industry mix of employment and state’s legacy industry mix.
Actual and Predicted Changes in Employment Rates
Implied by Changes in Fluidity, 1998-00 to 2010-11

```

```

“Predicted changes” refer to the employment rate changes implied by actual changes in reallocation intensity, according to our IV regression estimates, holding fixed national and state controls for cyclical conditions, state effects, and controls for children under 18 and under 5.
Are These Results Driven by the Great Recession? No

Re-estimating our baseline specifications using data that ends in 2007, and projecting pre-GR fluidity trends forward through 2011, we obtain similar results. For example, taking this approach and repeating the exercise on the previous slide yields a model-predicted decline of 7 percentage points from 1998 to 2011 in the employment rate for men with less than a high school education, as compared to an actual decline of 10 percentage points.
Actual and Predicted Changes in Employment Rates Implied by Changes in Fluidity, 1998-00 to 2010-11, By State (for 30 States Covered by QWI Data)

Actual and Predicted Changes in Employment Rates Implied by Changes in Fluidity, 1987-89 to 1999-01 And 1999-01 to 2008-10, By State (All 50 States)
Related Evidence from Other Studies

• The available evidence indicates that U.S. employers became less responsive to idiosyncratic shocks in recent decades, not that they experienced a fall in variability of idiosyncratic shocks.

• Job reallocation rates in high-tech industries rose in the 1990s, cutting against the prevailing pattern, but they fell sharply in these industries after 2000.

• Related, the high-tech sector experienced a large decline in startups and fast-growing young firms after 2000, reversing an earlier pattern.

• The frequency of IPOs in the United States plunged after 2000, following a robust pace of IPOs in the 1980s and 1990s.
