What is financial time series (FTS) analysis?

Theory and practice of asset valuation over time.

Different from other T.S. analysis?

Close, but with some added uncertainty. For example, FTS must deal with the ever-changing business & economic environment and the fact that volatility is not directly observed.

Objective of the course

- to provide some basic knowledge of financial time series data
- to introduce some statistical tools & econometric models useful for analyzing these series.
- to gain empirical experience in analyzing FTS
- to study methods for assessing market risk and expected loss
- to analyze high-dimensional asset returns.
Examples of financial time series

1. Daily log returns of GE stock

2. Quarterly earnings of Johnson & Johnson
   Seasonal time series useful in
   - earning forecasts
   - pricing weather related derivatives (e.g. energy)
   - modeling intraday behavior of asset returns

3. US monthly interest rates
   Relations between the two series? Term structure of interest rates

4. Exchange rate between US Dollar vs Japanese Yen
   Fixed income, hedging, carry trade

5. Size of insurance claims
   Values of fire insurance claims ($1000 Krone) that exceeded 500 from 1972 to 1992.

6. High-frequency financial data:
   Tick-by-tick data of Boeing stock: December 5, 2005.
Daily log returns of GE stock: 62-99

Figure 1: Daily log returns of GE stock
Quarterly earnings per share of Johnson & Johnson: 60-80

Figure 2: Quarterly earnings per share of Johnson and Johnson
Figure 3: Daily Exchange Rate: Dollar vs Yen

Figure 4: Daily log returns of FX (Dollar vs Yen)
(a) Monthly US interest rates: 10-year maturity

(b) 1-year maturity

Figure 5: Monthly US interest rates
Figure 6: Claim sizes of the Norwegian fire insurance from 1972 to 1992, measured in 1000 Krone and exceeded 500.

</table>
Outline of the course

• Returns & their characteristics: empirical analysis
• Simple linear time series models & their applications
• Univariate volatility modeling & its implications
• Nonlinearity in level and volatility
• Neural network & non-parametric methods
• High-frequency financial data and market micro-structure
• Continuous-time models and derivative pricing
• Value at Risk, extreme value theory and expected loss
• Analysis of multiple asset returns: factor models, dynamic and cross dependence

Asset Returns

Let $P_t$ be the price of an asset at time $t$, and assume no dividend.

One-period simple return: Gross return

$$1 + R_t = \frac{P_t}{P_{t-1}} \quad \text{or} \quad P_t = P_{t-1}(1 + R_t)$$

Simple return:

$$R_t = \frac{P_t}{P_{t-1}} - 1 = \frac{P_t - P_{t-1}}{P_{t-1}}.$$
Multiperiod simple return: Gross return

\[
1 + R_t(k) = \frac{P_t}{P_{t-k}} = \frac{P_t}{P_{t-1}} \times \frac{P_{t-1}}{P_{t-2}} \times \cdots \times \frac{P_{t-k+1}}{P_{t-k}} \\
= (1 + R_t)(1 + R_{t-1}) \cdots (1 + R_{t-k+1}).
\]

The \(k\)-period simple net return is \(R_t(k) = \frac{P_t}{P_{t-k}} - 1\).

**Example:** Suppose the daily closing prices of a stock are

<table>
<thead>
<tr>
<th>Day</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Price</td>
<td>37.84</td>
<td>38.49</td>
<td>37.12</td>
<td>37.60</td>
<td>36.30</td>
</tr>
</tbody>
</table>

1. What is the simple return from day 1 to day 2?
   Ans: \(R_2 = \frac{38.49 - 37.84}{37.84} = 0.017\).

2. What is the simple return from day 1 to day 5?
   Ans: \(R_5(4) = \frac{36.30 - 37.84}{37.84} = -0.041\).

3. Verify that \(1 + R_5(4) = (1 + R_2)(1 + R_3) \cdots (1 + R_5)\).

**Time interval** is important! Default is one year.

**Annualized (average) return:**

\[
\text{Annualized}[R_t(k)] = \left[ \prod_{j=0}^{k-1} (1 + R_{t-j}) \right]^{1/k} - 1.
\]

An approximation:

\[
\text{Annualized}[R_t(k)] \approx \frac{1}{k} \sum_{j=0}^{k-1} R_{t-j}.
\]
Continuously compounding: Illustration of the power of compounding (int. rate 10% per annum)

<table>

</tbody>
</table>

\[ A = C \exp[r \times n] \]

where \( r \) is the interest rate per annum, \( C \) is the initial capital, \( n \) is the number of years, and \( \exp \) is the exponential function.

**Present value:**

\[ C = A \exp[-r \times n] \]

**Continuously compounded (or log) return**

\[ r_t = \ln(1+R_t) = \ln \frac{P_t}{P_{t-1}} = p_t - p_{t-1}, \]

where \( p_t = \ln(P_t) \).

**Multiperiod log return:**

\[ r_t(k) = \ln[1+R_t(k)] = \ln[(1+R_t)(1+R_{t-1}) \cdots (1+R_{t-k+1})] \]
\[ \ln(1 + R_t) + \ln(1 + R_{t-1}) + \cdots + \ln(1 + R_{t-k+1}) = r_t + r_{t-1} + \cdots + r_{t-k+1}. \]

**Example** (continued). Use the previous daily prices.

1. What is the log return from day 1 to day 2?
   
   A: \( r_2 = \ln(38.49) - \ln(37.84) = 0.017. \)

2. What is the log return from day 1 to day 5?
   
   A: \( r_5(4) = \ln(36.3) - \ln(37.84) = -0.042. \)

3. It is easy to verify \( r_5(4) = r_2 + \cdots + r_5. \)

**Portfolio return**: \( N \) assets

\[ R_{p,t} = \sum_{i=1}^{N} w_i R_{it} \]

**Example**: An investor holds stocks of IBM, Microsoft and Citigroup. Assume that her capital allocation is 30%, 30% and 40%. Use the monthly simple returns in Table 1.2. What is the mean simple return of her stock portfolio?

**Answer**: \( E(R_t) = 0.3 \times 1.42 + 0.3 \times 3.37 + 0.4 \times 2.20 = 2.32. \)

**Dividend payment**:

\[ R_t = \frac{P_t + D_t}{P_{t-1}} - 1, \quad r_t = \ln(P_t + D_t) - \ln(P_{t-1}). \]

**Excess return**: (adjusting for risk)

\[ Z_t = R_t - R_{0t}, \quad z_t = r_t - r_{0t}. \]
where \( r_{0t} \) denotes the log return of a reference asset (e.g. risk-free interest rate).

**Relationship:**

\[
    r_t = \ln(1 + R_t), \quad R_t = e^{r_t} - 1.
\]

If the returns are in **percentage**, then

\[
    r_t = 100 \times \ln(1 + \frac{R_t}{100}), \quad R_t = [\exp(r_t/100) - 1] \times 100.
\]

Temporal aggregation of the returns produces

\[
    1 + R_t(k) = (1 + R_t)(1 + R_{t-1}) \cdots (1 + R_{t-k+1}),
\]

\[
    r_t(k) = r_t + r_{t-1} + \cdots + r_{t-k+1}.
\]

These two relations are important in practice, e.g. obtain annual returns from monthly returns.

**Example:** If the monthly log returns of an asset are 4.46\%, −7.34\% and 10.77\%, then what is the corresponding quarterly log return?

**Answer:** \( 4.46 − 7.34 + 10.77 = 7.89\% \).

**Example:** If the monthly simple returns of an asset are 4.46\%, −7.34\% and 10.77\%, then what is the corresponding quarterly simple return?

**Answer:** \( R = (1 + 0.0446)(1 − 0.0734)(1 + 0.1077) − 1 = 1.0721 − 1 = 0.0721 = 7.21\% \)
Distributional properties of returns

Key: What is the distribution of 
\{r_{it}; i = 1, \cdots, N; t = 1, \cdots, T}\? 

Some theoretical properties:

Moments of a random variable \(X\) with density \(f(x)\): \(\ell\)-th moment

\[m'_\ell = E(X^\ell) = \int_{-\infty}^{\infty} x^\ell f(x) dx\]

First moment: mean or expectation of \(X\).
\(\ell\)-th central moment

\[m_\ell = E[(X - \mu_x)^\ell] = \int_{-\infty}^{\infty} (x - \mu_x)^\ell f(x) dx,\]

2nd c.m.: Variance of \(X\).

Skewness (symmetry) and kurtosis (fat-tails)

\[S(x) = E \left[ \frac{(X - \mu_x)^3}{\sigma_x^3} \right], \quad K(x) = E \left[ \frac{(X - \mu_x)^4}{\sigma_x^4} \right].\]

\(K(x) - 3\): Excess kurtosis.

Why are mean and variance of returns important?
They are concerned with long-term return and risk, respectively.

Why is symmetry of interest in financial study?
Symmetry has important implications in holding short or long financial positions and in risk management.

Why is kurtosis important?
Related to volatility forecasting, efficiency in estimation and tests, etc.
High kurtosis implies heavy (or long) tails in distribution.

**Estimation:**

Data: \{x_1, \cdots, x_T\}

- sample mean:
  \[ \hat{\mu}_x = \frac{1}{T} \sum_{t=1}^{T} x_t, \]

- sample variance:
  \[ \hat{\sigma}_x^2 = \frac{1}{T - 1} \sum_{t=1}^{T} (x_t - \hat{\mu}_x)^2, \]

- sample skewness:
  \[ \hat{S}(x) = \frac{1}{(T - 1)\hat{\sigma}_x^3} \sum_{t=1}^{T} (x_t - \hat{\mu}_x)^3, \]

- sample kurtosis:
  \[ \hat{K}(x) = \frac{1}{(T - 1)\hat{\sigma}_x^4} \sum_{t=1}^{T} (x_t - \hat{\mu}_x)^4. \]

Under normality assumption,

\[ \hat{S}(x) \sim N(0, \frac{6}{T}), \quad \hat{K}(x) - 3 \sim N(0, \frac{24}{T}). \]

Some simple tests for normality (for large \(T\)).

1. Test for symmetry:
   \[ S^* = \frac{\hat{S}(x)}{\sqrt{6/T}} \sim N(0, 1) \]

   if normality holds.

   **Decision rule:** Reject \(H_o\) of a symmetric distribution if \(|S^*| > Z_{\alpha/2}\) or p-value is less than \(\alpha\).
2. Test for tail thickness:

\[ K^* = \frac{\hat{K}(x) - 3}{\sqrt{24/T}} \sim N(0, 1) \]

if normality holds.

Decision rule: Reject \( H_0 \) of normal tails if \(|K^*| > Z_{\alpha/2}\) or p-value is less than \( \alpha \).

3. A joint test (Jarque-Bera test):

\[ JB = (K^*)^2 + (S^*)^2 \sim \chi^2_2 \]

if normality holds, where \( \chi^2_2 \) denotes a chi-squared distribution with 2 degrees of freedom.

Decision rule: Reject \( H_0 \) of normality if \( JB > \chi^2_2(\alpha) \) or p-value is less than \( \alpha \).

Empirical properties of returns

Data sources:

- Course web:
  
  http://faculty.chicagogsb.edu/ruey.tsay/teaching/bs41202/sp2008/

- CRSP: Center for Research in Security Prices (via Wharton WRDS)
  
  http://wrds.wharton.upenn.edu/

- Various web sites, e.g. Federal Reserve Bank at St. Louis
  
  http://research.stlouisfed.org/fred2/
Data sets of the textbook:
http://faculty.chicagogsb.edu/ruey.tsay/teaching/fts2/

Empirical dist of asset returns tends to be skewed to the left with heavy tails and has a higher peak than normal dist. See Table 1.2 of the text.

Demonstration of Data Analysis

**R demonstration:** Use monthly IBM stock returns rom 1926 to 2007.

**** Task: (a) Set the working directory
(b) Load the library ‘‘fSeries’’ and library ‘‘fBasics’’.
(c) Compute summary statistics
(d) Perform test for mean return being zero.
(e) Perform normality test using the Jaque-Bera method.
(f) Perform skewness and kurtosis tests.

**Normal and lognormal dists**

$Y$ is lognormal if $X = \ln(Y)$ is normal.

If $X \sim N(\mu, \sigma^2)$, then $Y = \exp(X)$ is lognormal with mean and variance

\[
E(Y) = \exp(\mu + \frac{\sigma^2}{2}), \quad V(Y) = \exp(2\mu + \sigma^2)[\exp(\sigma^2) - 1].
\]
Conversely, if $Y$ is lognormal with mean $\mu_y$ and variance $\sigma^2_y$, then $X = \ln(Y)$ is normal with mean and variance

$$
E(X) = \ln \left( \frac{\mu_y}{\sqrt{1 + \frac{\sigma^2_y}{\mu_y^2}}} \right), \quad V(X) = \ln \left( 1 + \frac{\sigma^2_y}{\mu^2_y} \right).
$$

**Application:** If the log return of an asset is normally distributed with mean 0.0119 and standard deviation 0.0663, then what is the mean and standard deviation of its simple return?

**Answer:** Solve this problem in two steps.

**Step 1:** Based on the prior results, the mean and variance of $Y_t = \exp(r_t)$ are

$$
E(Y) = \exp \left[ 0.0119 + \frac{0.0663^2}{2} \right] = 1.014
$$

$$
V(Y) = \exp(2 \times 0.0119 + 0.0663^2) \left[ \exp(0.0663^2) - 1 \right] = 0.0045
$$

**Step 2:** Simple return is $R_t = \exp(r_t) - 1 = Y_t - 1$. Therefore,

$$
E(R) = E(Y) - 1 = 0.014
$$

$$
V(R) = V(Y) = 0.0045, \quad \text{standard dev} = \sqrt{V(R)} = 0.067
$$

**Remark:** See the monthly IBM stock returns in Table 1.2.

**Processes considered**

- return series (e.g., ch. 1, 2, 5)
- volatility processes (e.g., ch. 3, 4, 10, 12)
Likelihood function (for self study)
Finally, it pays to study the likelihood function of returns \( \{r_1, \cdots, r_T\} \) discussed in Chapter 1.

**Basic concept:**
Joint dist = Conditional dist \( \times \) Marginal dist, i.e.

\[
f(x, y) = f(x|y)f(y)
\]

For two consecutive returns \( r_1 \) and \( r_2 \), we have

\[
f(r_2, r_1) = f(r_2|r_1)f(r_1).
\]

For three returns \( r_1, r_2 \) and \( r_3 \), by repeated application,

\[
f(r_3, r_2, r_1) = f(r_3|r_2, r_1)f(r_2, r_1) = f(r_3|r_2, r_1)f(r_2|r_1)f(r_1).
\]

In general, we have

\[
f(r_T, r_{T-1}, \cdots, r_2, r_1)
\]

\[
= f(r_T|r_{T-1}, \cdots, r_1)f(r_{T-1}, \cdots, r_1)
\]

\[
= f(r_T|r_{T-1}, \cdots, r_1)f(r_{T-1}|r_{T-2}, \cdots, r_1)f(r_{T-2}, \cdots, r_1)
\]

\[
= \cdots
\]

\[
= \left[ \prod_{t=2}^{T} f(r_t|r_{t-1}, \cdots, r_1) \right] f(r_1),
\]
where $\prod_{t=2}^{T}$ denotes product.

If $r_t | r_{t-1}, \ldots, r_1$ is normal with mean $\mu_t$ and variance $\sigma_t^2$, then likelihood function becomes

$$f(r_T, r_{T-1}, \ldots, r_1) = \prod_{t=2}^{T} \frac{1}{\sqrt{2\pi \sigma_t}} \exp \left[ \frac{-(r_t - \mu_t)^2}{2\sigma_t^2} \right] f(r_1).$$

For simplicity, if $f(r_1)$ is ignored, then the likelihood function becomes

$$f(r_T, r_{T-1}, \ldots, r_1) = \prod_{t=2}^{T} \frac{1}{\sqrt{2\pi \sigma_t}} \exp \left[ \frac{-(r_t - \mu_t)^2}{2\sigma_t^2} \right].$$

This is the conditional likelihood function of the returns under normality.

Other dists, e.g. Student-$t$, can be used to handle heavy tails.

**Model specification**

- $\mu_t$: discussed in Chapter 2
- $\sigma_t^2$: Chapters 3 and 4.
Takeaway

1. Understand the summary statistics of asset returns
2. Understand various definitions of returns & their relationships
3. Learn basic characteristics of FTS.
Linear Time Series (TS) Models

Financial TS: collection of a financial measurement over time
Example: log return $r_t$

Data: $\{r_1, r_2, \ldots, r_T\}$ (T data points)
Purpose: What information contained in $\{r_t\}$?

Basic concepts

• Stationarity:
  – Strict: distributions are time-invariant
  – Weak: first 2 moments are time-invariant

What does weak stationarity mean in practice?
Past: time plot of $\{r_t\}$ varies around a fixed level within a finite range!
Future: the first 2 moments of future $r_t$ are the same as those of the data so that meaningful inferences can be made.

• Mean (or expectation) of returns:
  $$\mu = E(r_t)$$

• Variance (variability) of returns:
  $$\text{Var}(r_t) = E[(r_t - \mu)^2]$$
• Sample mean and sample variance are used to estimate the mean and variance of returns.

\[ \bar{r} = \frac{1}{T} \sum_{t=1}^{T} r_t \quad \& \quad \text{Var}(r_t) = \frac{1}{T - 1} \sum_{t=1}^{T} (r_t - \bar{r})^2 \]

• Test \( H_o : \mu = 0 \) vs \( H_a : \mu \neq 0 \). Compute

\[ t = \frac{\bar{r}}{\text{std}(\bar{r})} = \frac{\bar{r}}{\sqrt{\text{Var}(r_t)/T}} \]

Compare \( t \) ratio with \( N(0, 1) \) dist.

**Decision rule**: Reject \( H_o \) of zero mean if \(|t| > Z_{\alpha/2}\) or p-value is less than \( \alpha \).

• Lag-\( k \) autocovariance:

\[ \gamma_k = \text{Cov}(r_t, r_{t-k}) = E[(r_t - \mu)(r_{t-k} - \mu)] \]

• Serial (or auto-) correlations:

\[ \rho_\ell = \frac{\text{cov}(r_t, r_{t-\ell})}{\text{var}(r_t)} \]

Note: \( \rho_0 = 1 \) and \( \rho_k = \rho_{-k} \) for \( k \neq 0 \). Why?

Existence of serial correlations implies that the return is predictable, indicating market inefficiency.

• Sample autocorrelation function (ACF)

\[ \hat{\rho}_\ell = \frac{\sum_{t=1}^{T-\ell}(r_t - \bar{r})(r_{t+\ell} - \bar{r})}{\sum_{t=1}^{T}(r_t - \bar{r})^2} \]

where \( \bar{r} \) is the sample mean & \( T \) is the sample size.
• Test zero serial correlations (market efficiency)
  – Individual test: for example,
    \[ H_0 : \rho_1 = 0 \text{ vs } H_a : \rho_1 \neq 0 \]
    \[ t = \frac{\hat{\rho}_1}{\sqrt{1/T}} = \sqrt{T}\hat{\rho}_1 \]
    Asym. \( N(0, 1) \).
    **Decision rule**: Reject \( H_0 \) if \(|t| > Z_{\alpha/2}\) or p-value less than \( \alpha \).
  – Joint test (Ljung-Box statistics):
    \[ H_0 : \rho_1 = \cdots = \rho_m = 0 \text{ vs } H_a : \rho_i \neq 0 \]
    \[ Q(m) = T(T + 2) \sum_{\ell=1}^{m} \frac{\hat{\rho}_\ell^2}{T - \ell} \]
    Asym. chi-squared dist with \( m \) degrees of freedom.
    **Decision rule**: Reject \( H_0 \) if \( Q(m) > \chi^2_m(\alpha) \) or p-value is less than \( \alpha \).

• Sources of serial correlations in financial TS
  – Nonsynchronous trading (ch. 5)
  – Bid-ask bounce (ch. 5)
  – Risk premium, etc. (ch. 3)

Thus, significant sample ACF does not necessarily imply market inefficiency.

**Example**: Monthly returns of IBM stock from 1926 to 1997.
• $R_t$: $Q(5) = 5.4(0.37)$ and $Q(10) = 14.1(0.17)$

• $r_t$: $Q(5) = 5.8(0.33)$ and $Q(10) = 13.7(0.19)$

**Remark:** What is p-value? How to use it?

Implication: Monthly IBM stock returns do not have significant serial correlations.

**Example:** Monthly returns of CRSP value-weighted index from 1926 to 1997.

• $R_t$: $Q(5) = 27.8$ and $Q(10) = 36.0$

• $r_t$: $Q(5) = 26.9$ and $Q(10) = 32.7$

All highly significant. Implication: there exist significant serial correlations in the equal-weighted index returns. (Nonsynchronous trading might explain the existence of the serial correlations, among other reasons.)

**R demonstration:** IBM monthly simple returns from 1926 to 2007.

```r
> library('fSeries')
> x=read.table("m-ibm2607.txt")
> ibm=x[,2] % 2nd column of the data file.
> acf(ibm,lag=15) % Obtain the ACF plot
> s1=acf(ibm,lag=15) % Obtain the ACF plot and more.
> names(s1)
[1] "acf" "type" "n.used" "lag" "series" "snames"

> s1$acf
     [,1]    [,2]    [,3]

\text{Box-Ljung test} \\
data: \text{ibm} \\
X\text{-squared} = 13.7108, \ df = 10, \ p\text{-value} = 0.1866
\end{array}
\]

**Splus demonstration:** IBM monthly simple returns from 1926 to 2007.

\[ > \text{module}('\text{finmetrics}') \]
\[ > x = \text{read.table(''m-ibm2607.txt'')} \]
\[ > ibm = x[,2] \] % 2nd column is the simple returns.
\[ > \text{acf}(ibm, \text{lag.max}=15) \] % Obtain ACF plot and values.
Call: \[ \text{acf}(x = \text{ibm}, \text{lag.max} = 15) \]

Autocorrelation matrix:
lag  ibm
1  0  1.0000
2  1  0.0358
3  2 -0.0113
4  3 -0.0172
5  4 -0.0317
(edited)
14 13 -0.0629
15 14 -0.0123
16 15 -0.0390

> acf(ibm,type='partial')  % Obtain Partial ACF and plot.
Call: acf(x = ibm, type = "partial")

Partial Correlation matrix:

  lag  ibm
  1  1  0.0358
  2  2 -0.0126
  3  3 -0.0163
  4  4 -0.0307
(edited)
  14 14 -0.0031
  15 15 -0.0384

> autocorTest(ibm,lag=10)  % Obtain Ljung-Box Q(10) test

Test for Autocorrelation: Ljung-Box

Null Hypothesis: no autocorrelation

Test Statistics:

Test Stat 13.7108
  p.value  0.1866

Dist. under Null: chi-square with 10 degrees of freedom
  Total Observ.: 984
Back-shift (lag) operator
A useful notation in TS analysis.

- Definition: $B r_t = r_{t-1}$ or $L r_t = r_{t-1}$
- $B^2 r_t = B(B r_t) = B r_{t-1} = r_{t-2}$.

$B$ (or $L$) means time shift! $B r_t$ is the value of the series at time $t - 1$.

Suppose that the daily log returns are

<table>
<thead>
<tr>
<th>Day</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>$r_t$</td>
<td>0.017</td>
<td>-0.005</td>
<td>-0.014</td>
<td>0.021</td>
</tr>
</tbody>
</table>

Answer the following questions:

- $r_2 =$
- $B r_3 =$
- $B^2 r_5 =$

Question: What is $B^2$?

What are the important statistics in practice?
Conditional quantities, not unconditional

A proper perspective: at a time point $t$

- Available data: $\{r_1, r_2, \cdots, r_{t-1}\} \equiv F_{t-1}$
The return is decomposed into two parts as
\[ r_t = \text{predictable part} + \text{not predic. part} \]
\[ = \text{function of elements of } F_{t-1} + a_t \]

In other words, given information \( F_{t-1} \)
\[ r_t = \mu_t + a_t \]
\[ = E(r_t|F_{t-1}) + \sigma_t \epsilon_t \]

- \( \mu_t \): conditional mean of \( r_t \)
- \( a_t \): shock or innovation at time \( t \)
- \( \epsilon_t \): an iid sequence with mean zero and variance 1
- \( \sigma_t \): conditional standard deviation (commonly called volatility in finance)

Traditional TS modeling is concerned with \( \mu_t \):
Model for \( \mu_t \): **mean equation**
Volatility modeling concerns \( \sigma_t \).
Model for \( \sigma_t^2 \): **volatility equation**

**Univariate TS analysis serves two purposes**

- a model for \( \mu_t \)
- understanding models for \( \sigma_t^2 \): properties, forecasting, etc.

**Linear time series**: \( r_t \) is linear if
• the predictable part is a linear function of $F_{t-1}$

• \{a_t\} are indep. and have the same dist. (iid)

Mathematically, it means $r_t$ can be written as

$$r_t = \mu + \sum_{i=0}^{\infty} \psi_i a_{t-i},$$

where $\mu$ is a constant, $\psi_0 = 1$ and \{a_t\} is an iid sequence with mean zero and well-defined distribution.

In the economic literature, $a_t$ is the shock (or innovation) at time $t$ and \{\psi_i\} are the impulse responses of $r_t$.

**White noise**: iid sequence (with finite variance), which is the building block of linear TS models.

White noise is not predictable, but has zero mean and finite variance.

**Univariate linear time series models**

1. autoregressive (AR) models

2. moving-average (MA) models

3. mixed ARMA models

4. seasonal models

5. regression models with time series errors

6. fractionally differenced models (long-memory)
Example Quarterly growth rate of U.S. real gross national product (GNP), seasonally adjusted, from the second quarter of 1947 to the first quarter of 1991.

An AR(3) model for the data is

\[ r_t = 0.005 + 0.35r_{t-1} + 0.18r_{t-2} - 0.14r_{t-3} + a_t, \quad \hat{\sigma}_a = 0.01, \]

where \( \{a_t\} \) denotes a white noise with variance \( \sigma_a^2 \). Given \( r_n, r_{n-1} \& r_{n-2} \), we can predict \( r_{n+1} \) as

\[ \hat{r}_{n+1} = 0.005 + 0.35r_n + 0.18r_{n-1} - 0.14r_{n-2}. \]

Other implications of the model?
**Example:** Monthly simple return of CRSP equal-weighted index

\[ R_t = 0.013 + a_t + 0.178a_{t-1} - 0.13a_{t-3} + 0.135a_{t-9}, \quad \hat{\sigma}_a = 0.073 \]

Checking: \( Q(10) = 11.4(0.122) \) for the residual series \( a_t \).

Implications of the model?

**Important properties of a model**

- Stationarity condition
- Basic properties: mean, variance, serial dependence
- Empirical model building: specification, estimation, & checking
- Forecasting
